

# Discrete Differential Geometry

Paolo Cignoni

[paolo.cignoni@isti.cnr.it](mailto:paolo.cignoni@isti.cnr.it)

<http://vcg.isti.cnr.it/~cignoni>

# Normal

▣ Let's consider 2 manifold surface  $S$  in  $\mathbb{R}^3$

▣ Suppose to have a mapping  $\mathbb{R}^2 \rightarrow \mathbb{R}^3$

$$S(u,v) \rightarrow \mathbb{R}^3$$

▣ Then we can define the normal for each point of the surface as:

$$\mathbf{n} = (\mathbf{x}_u \times \mathbf{x}_v) / \|\mathbf{x}_u \times \mathbf{x}_v\|$$

Where  $X_u$  and  $X_v$  are vectors on tangent space

# Normal

□ Normal  $\mathbf{n} = (\mathbf{x}_u \times \mathbf{x}_v) / \|\mathbf{x}_u \times \mathbf{x}_v\|$

# Normals on triangle meshes

- ❖ Computed per-vertex and interpolated over the faces
- ❖ Common: consider the tangent plane as the average among the planes containing all the faces incident on the vertex

$$n_v = \frac{1}{\#N(v)} \sum_{f \in N(v)} n_f$$
$$N(v) = \{f : f \text{ coface of } v\}$$

# Normals on triangle meshes

- ❖ Does it work? Yes, for a “good” tessellation
- ❖ Small triangles may change the result dramatically
- ❖ Weighting by area, angle, edge len helps
  - ❖ Note: if you get the normal as cross product of adj edges, if you leave it un-normalized its length is twice the area of the triangle -> *you can get the area weighting for free*

# Curvature

- Define a tangent vector  $\mathbf{t} = \cos \phi \frac{\mathbf{x}_u}{\|\mathbf{x}_u\|} + \sin \phi \frac{\mathbf{x}_v}{\|\mathbf{x}_v\|}$

# Curvature

- Consider the plane along  $n, t$  and the 2D curve defined on it

# Curvature in 2D

- The curvature of  $C$  at  $P$  is then defined to be the reciprocal of the radius of osculating circle at point  $P$ .

The osculating circle of a curve  $C$  at a given point  $P$  is the circle that has the same **tangent** as  $C$  at point  $P$  as well as the same **curvature**.

Just as the tangent line is the line best approximating a curve at a point  $P$ , the osculating circle is the best circle that approximates the curve at  $P$

# Main curvature directions

- For each direction  $\mathbf{t}$ , we define a curvature value.
- Let's consider the two directions  $\mathbf{k}_1$  and  $\mathbf{k}_2$  where the curvature values are **maximum** and **minimum**
- Orient them such that the cross product is along the normal

# Gaussian curvature

- Defined as  $K = k_1 \cdot k_2$ 
  - $> 0$  when the surface is a sphere
  - $0$  if locally flat
  - $< 0$  for hyperboloids

# Gaussian curvature

□ A point  $x$  on the surface is called:

□ **elliptic** if  $K > 0$

( $k_1$  and  $k_2$  have the same sign)

□ **hyperbolic** if  $K < 0$

( $k_1$  and  $k_2$  have opposite sign)

□ **parabolic** if  $K = 0$

(exactly one of  $k_1$  and  $k_2$  is zero)

□ **planar** if  $K = 0$

(equivalently  $k_1 = k_2 = 0$ ).

elliptic

hyperbolic

parabolic

planar

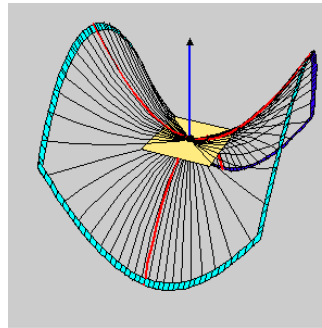

# Different classes distributed on the surface

elliptic

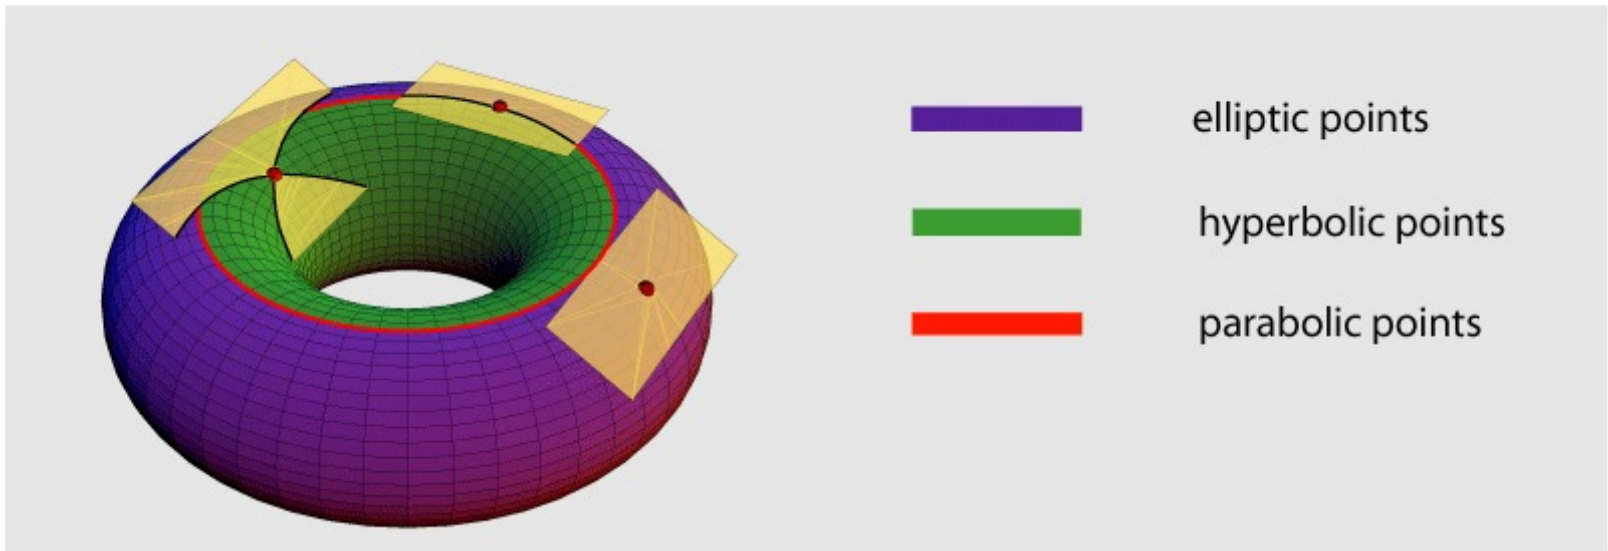

parabolic

hyperbolic

planar

# Developable surfaces

- ▣ Developable surface  $\Leftrightarrow K = 0$
- ▣ Flattening introduce no distortion

# Gaussian Curvature: intrinsic / extrinsic

□ Gaussian curvature is an **intrinsic** property of the surface (even if we defined it in an extrinsic way)

□ It is possible to determine it by moving on the surface keeping the geodesic distance constant to a radius  $r$  and measuring the circumference  $C(r)$  :

$$K = \lim_{r \rightarrow 0} \frac{6\pi r - 3C(r)}{\pi r^3}$$

$K > 0$

$K < 0$

# Mean Curvature

□  $H = (k_1 + k_2) / 2$

□ Measure the **divergence** of the normal in a local neighborhood of the surface

□ The **divergence**  $\text{div}_s$  is an operator that measures a vector field's tendency to originate from or converge upon a given point

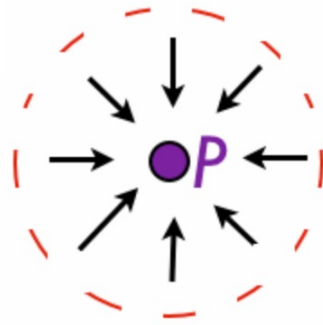

# Divergence

Imagine a vector field represents water flow:

- If  $\text{div}_s$  is a **positive** number, then water is **flowing out** of the point.
- If  $\text{div}_s$  is a **negative** number, then water is **flowing into** the point.

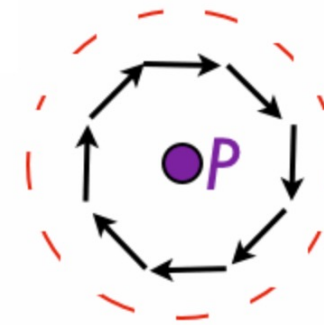

$$\text{div}_s > 0$$

$$\text{div}_s > 0$$

$$\text{div}_s = 0$$

$$\text{div}_s = 0$$

$$\text{div}_s > 0$$

# Minimal surface and minimal area surfaces

- A surface is **minimal** iff  $H=0$  everywhere
- All surfaces of minimal AREA (subject to boundary constraints) have  $H=0$  (not always true the opposite!)
- The surface tension of an interface, like a soap bubble, is proportional to its mean curvature

# Then... finally...

■ Red  $> 0$  Blue  $< 0$  , not the same scale

max

## Some math.... Gradient and divergence

□ Given a function  $F: \mathbb{R}^2 \rightarrow \mathbb{R}$  (our surface) the **gradient** of  $F$  is the vector field  $\nabla F: \mathbb{R}^2 \rightarrow \mathbb{R}^2$  defined by the partial derivatives:

$$\nabla F(x, y) = \left( \frac{\partial F}{\partial x}, \frac{\partial F}{\partial y} \right)$$

□ **Intuitively:** At the point  $p_0$ , the vector  $\nabla F(p_0)$  points in the **direction of greatest change of  $F$** .

# Some math... Gradient and divergence

Example :

$$F(x, y) = x^2 + y^2$$

$$F(x, y) = xy$$

$$\nabla F(x, y) = (2x, 2y)$$

$$\nabla F(x, y) = (y, x)$$

## Some math.... Gradient and divergence

□ Given a function  $\mathbf{F}(F_1, F_2): \mathbb{R}^2 \rightarrow \mathbb{R}^2$  the **divergence** of  $\mathbf{F}$  is the function **div**:  $\mathbb{R}^2 \rightarrow \mathbb{R}$  defined as:

$$\text{div } \mathbf{F}(x, y) = \partial F_1 / \partial x + \partial F_2 / \partial y$$

□ **Intuitively**: At the point  $p_0$ , the divergence  $\text{div } \mathbf{F}(p_0)$  is a measure of the extent to which the flow (de)compresses at  $p_0$ .

# Some math... Gradient and divergence

$$F(x, y) = x^2 + y^2$$

$$F(x, y) = xy$$

$$\nabla F(x, y) = (2x, 2y)$$

$$\text{div } \nabla F(x, y) = 4$$

$$\nabla F(x, y) = (y, x)$$

$$\text{div } \nabla F(x, y) = 0$$

## Some math.... Laplacian

□ Given a function  $\mathbf{F}(F_1, F_2): \mathbb{R}^2 \rightarrow \mathbb{R}$

the **Laplacian** of  $\mathbf{F}$  is the function  $\Delta \mathbf{F}: \mathbb{R}^2 \rightarrow \mathbb{R}$  defined by the divergence of the gradient of the partial derivatives:

$$\Delta F = \operatorname{div}(\nabla F(x, y)) = \partial^2 F / \partial x^2 + \partial^2 F / \partial y^2$$

□ **Intuitively:** The Laplacian of  $F$  at the point  $p_0$  measures the extent to which the value of  $F$  at  $p_0$  differs from the average value of  $F$  its neighbors.

# Discrete Laplacian

## □ Cotangent formula

$$\Delta_{\mathcal{S}} f(v) := \frac{2}{A(v)} \sum_{v_i \in \mathcal{N}_1(v)} (\cot \alpha_i + \cot \beta_i) (f(v_i) - f(v))$$

# Discrete Curvatures

□ Mean Curvature  $H = \|\Delta_S \mathbf{x}\|$

□ Gaussian Curvature  $G = (2\pi - \sum_j \theta_j) / A$

□ Principal Curvatures

$$\kappa_1 = H + \sqrt{H^2 - G}$$

$$\kappa_2 = H - \sqrt{H^2 - G}$$

# Mean curvature on a triangle mesh

$$H(p) = \frac{1}{2A} \sum (cot\alpha_i + cot\beta_i) \|p - p_i\|$$

where  $\alpha_j$  and  $\beta_j$  are the two angles opposite to the edge in the two triangles having the edge  $e_{ij}$  in common

$A$  is the sum of the areas of the triangles

# Gaussian curvature on a triangle mesh

❖ It's the *angle defect* over the area

❖

$$\kappa_G(v_i) = \frac{1}{3A} \left( 2\pi - \sum_{t_j \text{ adj } v_i} \theta_j \right)$$

❖ **Gauss-Bonnet Theorem:** The integral of the Gaussian Curvature on a closed surface depends on the Euler number

$$\int_S \kappa_G = 2\pi \chi$$

# Discrete Curvatures

## □ Problems:

- Depends on triangulation!
- Very sensitive to Noise...

# Curvature via Surface Fitting

- The radius  $r$  of the neighborhood of each point  $p$  is used as a scale parameter
  - 1. gather all faces in a local neighborhood of radius  $r$
  - 2. set an axis  $\mathbf{w} = \frac{1}{n_v} \sum_{i=1}^n \mathbf{n}_i$
- where  $n_v$  is the number of vertices gathered and  $n_i$  is the surface normal at each such vertex

# Curvature via Surface Fitting

- 3. discard all vertices  $v_i$  such that  $n_i \cdot w < 0$
- 4. set a local frame  $(u, v, w)$  where  $u$  and  $v$  are any two orthogonal unit vectors lying on the plane orthogonal to  $w$ , and such that the frame is right-handed
- 5. express all vertices of the neighborhood in such a local frame with origin at  $\mathbf{p}$
- 6. fit to these points a polynomial of degree two through  $\mathbf{p}$  (least squares fitting)

$$f(u, v) = au^2 + bv^2 + cuv + du + ev$$

- Curvatures at  $\mathbf{p}$  are computed **analytically via first and second fundamental forms** of  $f$  at the origin

# curvature via surface fitting

- Curvatures extracted at different scales

# Curvature Directions(VCG)

Both per Face and per Vertex

```
class MyTriVertex:public vcg::Vertex<TriUsedTypes...,vcg::vertex::CurvatureDir, ... >{};

class MyTriFace:public vcg::Face<TriUsedTypes...,vcg::face::CurvatureDir,... >{};
```

Access main directions

```
MyTriVertex *v= ...;
Vcg::Point3d Dir1=v->PD1();
Vcg::Point3d Dir2=v->PD2();
ScalarType Norm1=v->K1();
ScalarType Norm2=v->K2();
```

Accessing mean and gaussian

```
MyTriVertex *v= ...;
Vcg::Point3d Dir1=v->Kh();
Vcg::Point3d Dir2=v->Kg();
```

Draw

```
#include <wrap/gl/gl_field.h>
vcg::GLField<MyTriMesh>::GLDrawFaceField(m);
```

# Discrete Curvature Mean & Gaussian (VCG)

vcg/complex/algorithms/update/curvature.h

```
namespace vcg {  
namespace tri  
{  
  
    template <class MeshType>  
    class UpdateCurvature  
    {  
        void MeanAndGaussian(MeshType & m)  
    };  
}  
}
```

- Noisy result
- Dependent on the triangulation
