

A mesh processing library

Paolo Cignoni

ISTI – CNR

Intro

- ▣ Intro
- ▣ Capabilities
- ▣ Design/Structure
- ▣ Examples

What

- A C++ template based library
 - Include only, no compilation hassle
- Research Driven Library
 - The most amatorial professional library
- A rather rich and hopefully easy to use library for mesh processing
- The core of the well known MeshLab system.

Where

- Main site:
 - <http://vcglib.net>
- The code
 - No rigid release scheme
 - Sync with meshlab releases
 - Just clone the git repo
 - USE the **DEVEL** branch (
- Documentation by doxygen on the web
- A bunch of small samples
 - `vcglib/apps/sample`

Capabilities

- VCG library feature a large number of different algorithms
- In the next slides a fast browsing of some of the most known things in the library

Simplification

- Fairly generic edge collapse simplification algorithms
- Probably one of the reason meshlab is famous.
- Link conditions for topology preserving
 - Two optimized specializations
 - Quadric error (with a few minor variants)
 - Quadric error with texture coords optimization.

Sampling

- A variety of algorithm for distributing points over the surface of a mesh
 - a reasonably practical and fast adaptive poisson sampling algorithm.
 - Unbiased montecarlo
 - Useful for computing sampled integral measures over meshes

Cleaning

- A variety of tools for correcting small annoying things
 - Duplicated, unreferenced mesh elements
 - Merging of close vertices
 - Small hole filling
 - Non manifold detection and correction
 - Split of non manifold vertexes
 - Heuristic Deletion of isolated non manifold faces

Color Processing

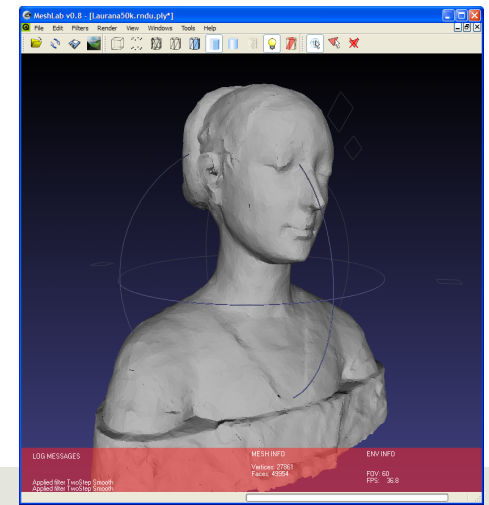

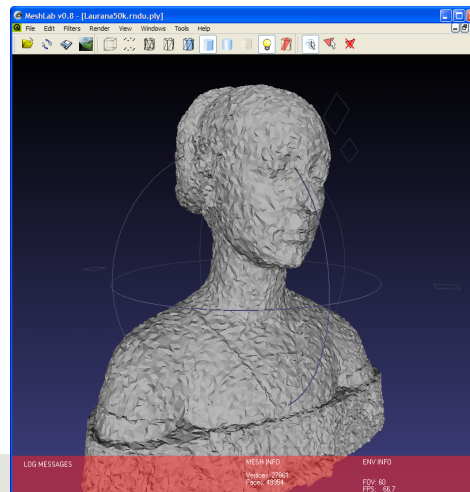

- VCG support color in various format
 - Per vertex
 - Per face
 - Per wedge
 - As texture
- Provides tools for converting from a representation to another one.

Measuring

- Integral measures
 - Volume, barycenter inertia tensor
- Distance between surfaces
 - Sampled Hausdorff distance
- Distance and intersection between a lot of geometric elements
 - (point-triangle, triangle-triangle etc)

Smoothing

- A number of sophisticated noise removal tools.
- Basic laplacian (with or without cotangent weighting)
- Taubin smoothing
- Two step feature preserving smoothing.
- A number of smoothing algorithms can also be applied to various attributes like color, normal, scalar field over the mesh

Texturing

- Support of per vertex and per wedge text coords
- Conversion between representations
- Packing algorithms
- Various texture optimization

Remeshing

- Subdivision surfaces
 - (loop, butterfly)
 - Generic
 - Define your own predicate to decide if an edge has to be split and where.
- Ball Pivoting surface reconstruction
- Clustering simplification
- Marching cubes

Spatial Indexing

- Uniform Grid
 - Very good if your query points are quite near to the surface
- Kd-tree
 - Perfect for point clouds
- Hierarchies of Bounding Volumes

File Format

- VCGLib provides importer and exporter for several file formats:
- import:
 - PLY, STL, OFF, OBJ, 3DS, COLLADA, PTX, V3D, PTS, APTS, XYZ, GTS, TRI, ASC, X3D, X3DV, VRML, ALN
- export:
 - PLY, STL, OFF, OBJ, 3DS, COLLADA, VRML, DXF, GTS, U3D, IDTF, X3D
- Caveat it flattens everything to a polygon soup.
 - No scene graph information is retained for the most complex formats

Basic Concepts: The Mesh

- encode a mesh in several ways,
- the most common is a vector of vertices and vector of triangles.
- The following line is an example of the definition of a VCG type of mesh:

```
class MyMesh :  
    public vcg::tri::TriMesh<  
        std::vector<MyVertex> ,  
        std::vector<MyFace> ,  
        std::vector<MyEdge> > {};
```

- you need only to derive from `vcg::tri::TriMesh` and to provide the type of containers of the elements

Basic Concepts: The simplexes 2

- Caveat first of all you have to pre-declare what are the intended names for the various pieces

```
struct MyUsedTypes : public
    vcg::UsedTypes<
        vcg::Use<MyVertex>      ::AsVertexType,
        vcg::Use<MyEdge>        ::AsEdgeType,
        vcg::Use<MyFace>        ::AsFaceType>{ };
```

- In this way when you are declaring a vertex you already know what are the types involved in mixed relations like the vertex type adjacency

Basic Concepts: Using the mesh

- Most of the stuff in the library came in the shape of static templated class;
- Most of the time you see stuff like

```
vcg::tri::UpdateNormal<MyMesh>::PerVertexNormalized(m);
```

Capabilities

- ▣ We could continue...
- ▣ MeshLab filters
 - ▣ Exposed more than a hundred high level filtering tools.
 - ▣ Most of them directly maps into vcg libs functions or classes.

Example 1: trimesh_base

- Basic example of minimal use
- Load a mesh and just dump some info about it
- Note that also the mesh loading is done by mean of templated class.

Basic Concept: Adjacency

- Vertex, Edge and triangle can store different topological info:
- The most common is the VertexRef field of the face, that store for each triangular face three ptr to its vertexes
- Other commonly used relations are
- FF face face relation
- VF vertex face relation

- `tri::UpdateTopology<MyMesh>::FaceFace(m);`
- `tri::UpdateTopology<MyMesh>::VertexFace(m);`

Basic Concept: Adjacency

- FF relation works for non manifold situations
faces around an edge are ring connected

- VF relation does not involve
any dynamic allocation,
the chain of face is distributed
onto the involved face

Basic Concepts: Navigating

- The Pos is the VCG Lib implementation of the Cell-Tuple and it abstracts the concept of position over a mesh
- A Pos in a triangle mesh is a triple made of
 $\text{pos} = (v, e, f)$
- For manifold meshes there are flip operators that allow easy navigation on the mesh
 - FlipV, FlipE, FlipF
- Each flip operator, applied to a pos simply changes only the indicated element
 - $c2 = c1.\text{FlipV}()$
 - $c0 = c1.\text{FlipE}()$
 - $c3 = c0.\text{FlipF}()$

Basic Concept: Navigating

- There are also classical retrieval functions:
- `vcg::face::VFOrderedStarFF`
 - Compute the ordered set of faces adjacent to a given vertex using FF adjacency
- `vcg::face::VVStarVF`
- `vcg::face::VFStarVF`
- `vcg::face::VFExtendedStarVF`
- `vcg::face::EFStarFF`

Example 2: trimesh_topology

- Note the `face::FFAdj` component in the face
- Note on marking
 - Simplex can have a mark component (`face::Mark`) that offers $O(1)$ unmark of the whole mesh. Implemented by mean of counters, useful to avoid the usually required $O(n)$ clearing.
- If your simplex has bitflags, you have also standard visiting/selection bits

Basic Concept: Allocation

- Simplex are kept into vectors
- Relations are kept by mean of pointers
- Pay attention to reallocations...
 - Always use the library functions to manage the simplex vectors

```
MyMesh::VertexIterator vi = tri::Allocator<MyMesh>::AddVertices(m,3);  
MyMesh::FaceIterator fi = tri::Allocator<MyMesh>::AddFaces(m,1);
```

Basic Concept: De-Allocation

- The library adopts a Lazy Deletion Strategy
 - i.e. the elements in the vector that are deleted are only flagged as deleted, but they are still there.
 - `m.vert.size() != m.VN()`
 - `m.face.size() != m.FN()`
- Therefore when you scan the containers of vertices and faces you could encounter deleted elements
- You can get rid of deleted elements by explicitly calling the two garbage collecting functions:

```
vcg::tri::Allocator<MyMesh>::CompactFaceVector(m);
```

```
vcg::tri::Allocator<MyMesh>::CompactVertexVector(m);
```

Example 3: trimesh_allocate

- Note
- How to simply build a minimal mesh from scratch
- the use of the PointerUpdater to cope with vector reallocation
- The use of explicit function to copy a mesh onto another
- The pitfall of having deleted elements

Basic Concept: Reflection

- VCG Lib provides a set of functions to implement reflection,
 - i.e. to investigate the type of a mesh at runtime
- These functions follow the format
 - `tri::Has[attribute](mesh)`
 - `tri::HasPerVertexNormal(m);`
 - `tri::HasPerFaceColor(m);`
 - etc...
- Return a boolean stating if that particular attribute is present or not
- These functions are not statically typed and need the mesh object because of optional stuff...
 - But they are statically solved if no optional stuff arise in your code

Basic Concept: Requiring data

- Reflection is often used to check the availability of component for a given algorithm
- For example
 - subdivision surface algorithms require FF adjacency
 - Simplification require VF adjacency and per vertex marks
 - Etc.
- If something is missing an exception is raised
- `Tri::RequireFFAdjacency(mesh);`
 - Raise a **missing component** exception if the FF adj is missing

Basic Concept: Optional Component

- Simplex components imply storage
 - E.g. FF adjacency means 4 words per face.
 - Components are stored into the simplex type
- Most components can be done optional
 - E.g. you can control the allocation space of that component at runtime

```
class CFaceOcf      : public vcg::Face< MyUsedTypesOcf,  
    vcg::face::InfoOcf, vcg::face::FFAdjOcf,  
    vcg::face::VertexRef, vcg::face::BitFlags,  
    vcg::face::Normal3fOcf > {};
```

```
class CMeshOcf      : public vcg::tri::TriMesh<  
    vcg::vertex::vector<CVertex>,  
    vcg::face::vector_ocf<CFaceOcf> > {};
```

Basic Concept: Optional Component

- Storage of optional component is separated
 - E.g. The data for the FF adjacency is stored in a 'parallel' vector alongside the face vector.
- Access is exactly the same.
- You explicitly control the allocation

```
assert(tri::HasFFAdjacency(cmof) == false);  
cmof.face.EnableFFAdjacency();  
assert(tri::HasFFAdjacency(cmof) == true);
```

Example4: trimesh_optional

- Note the different definition of the type
- Note the enabling of the needed components
- Try to raise exceptions by commenting out the needed enabling

Basic Concept: User Def Attribute

- VCG Lib provides a mechanism to associate **user-defined 'attributes'** to the simplicies and to the mesh
- Attribute vs Components
 - Components are conceptually inside the simplex
 - `(*vi).N();`
 - Attributes need an handle to be accessed
 - `irradHandle[vi];`
- To use an attribute
 - Build an handle (find or create the attribute)
 - Use the handle to access the data

Basic Concept: User Def Attribute

■ Getting a named attribute handle

```
MyMesh::PerVertexAttributeHandle<float> named_hv =  
    vcg::tri::Allocator<MyMesh>::GetPerVertexAttribute<float>  
        (m, std::string("Irradiance"));
```

■ Using an handle

```
MyMesh::VertexIterator vi; int i = 0;  
for(vi = m.vert.begin(); vi != m.vert.end(); ++vi, ++i)  
{  
    named_hv[vi]    = 1.0f;    // [] operator takes a iterator  
    named_hv[*vi]  = 1.0f;    // or a MyMesh::VertexType object  
    named_hv[&*vi]= 1.0f;    // or a pointer to it  
    named_hv[i]    = 1.0f;    // or an integer index  
}
```

Basic Concept: *ForEach* construct

- to traverse all the vertexes of a mesh you can simply write something like:

```
ForEachVertex(m, [&](const VertexType &v){  
    MakeSomethingWithVertex(v);  
});
```

- There are similar constructs for edges and faces
- Main advantage, avoid verbose checking of deleted elements

```
MyMesh::VertexIterator vi;  
for(vi = m.vert.begin(); vi != m.vert.end(); ++vi, ++i)  
{  
    if(!vi->IsD())  
    {  
        MakeSomethingWithVertex(v);  
    }  
}
```

Example5: trimesh_attribute

- Note the creation/test/delete functions
- Note the multiple way of accessing thru handles
